SUMMARY
At present, this early in the winter crop growing season, starting soil water conditions and the seasonal rainfall outlook indicate that chances are for a close to average wheat yield during the 2021 wheat-growing season at an aggregated state (QLD) level. However, a large variation in predicted yield outcomes exists within the state’s cropping region. Specifically, while most parts of QLD have chances similar to climatology (50:50) for an above average wheat yield, some parts of SEQ and SWQ have slightly increased chances of this year’s wheat crop being above the long-term median for that region. This early in the season, widespread above average rainfall is needed across all parts of the state’s cropping region during the next couple of months. This is needed to induce good planting opportunities and improve current winter cropping conditions across the state. However, the likely range of yield outcomes is still very wide. This range will narrow considerably over the next few months as the outlook is updated through the season.

GENERAL CONDITIONS
Rainfall recorded during May 2021 was variable throughout the state’s winter cropping region. Specifically, most parts of southern received average to above average rainfall, while most of CQ and SWQ received below average rainfall. Furthermore, rainfall recorded during the six months from December 2020 to end of May 2021, was average to above average across almost the entire state’s cropping region. This has resulted in available soil water levels to recharge to above 60% of the potential available water content (PAWC) for almost all of that region. The exception was for some parts of CQ and northern SEQ, which mostly recorded below average rainfall and therefore replenishment of soil moisture levels close to 50% of PAWC for most of that region (Map 2).

The recent pattern of the SOI, “near zero” for the April-May period, indicates a slightly increased chance for above average rainfall in most parts of the state’s winter cropping region over the next 3-months (www.longpaddock.qld.gov.au). However, this will change depending on the movement in the SOI as the season progresses over the next month. Crops sown into profiles with low soil water are more dependent on in-crop rainfall, and in such situations, forecasts based on SOI phases can be most useful. At this stage, atmospheric indicators for ENSO are in a NEUTRAL mode. Progress of the climate indicators such as the SOI and sea surface temperature anomalies can be followed here (www.bom.gov.au/climate/enso).

OUTLOOK
This regional wheat crop outlook assumes cropping after summer fallow. The benchmark for this outlook is the simulated long-term median shire wheat yield within the broad cropping region of Queensland (Map 1). The median yield is based on predicted performance over the past 121-years using an agro-climatic model for wheat with long-term rainfall records (see descriptive note for more details). The probability of exceeding the long-term median shire wheat yield for the coming season is shown in Map 3. Any areas coloured in yellow to red have a reduced chance of exceeding the median yield, whereas areas coloured in green to blue have an increased chance.
Map 3 is derived by considering conditions up to the end of May and projecting forward based on rainfall conditions in years from the historical record with SOI phase like this year - “near zero” in April/May. The calculation of benchmark yields and outlook chances do not consider effects of poor crop nutrition or damage due to pests, diseases, frosts, or extreme events. This outlook is derived assuming only a summer (short) fallow period. The current state wheat outlook, at this very early stage in the season, varies across most of the state’s cropping area. Specifically, equal chances exist (50:50) of exceeding the long-term median yield for most parts QLD winter cropping region. The exception is for some parts of SEQ and northern CQ having slightly increased chances (60% to 80%) of exceeding the long-term shire yield expectation. It is anticipated that area planted to winter crops will increase from last winter season in most parts of QLD, mainly due to the previously drier than average summer and winter seasons experienced. However, widespread above average rainfall during the next few months is needed to induce plantings and improve the current wheat yield outlook for most of the state’s winter cropping region.

It should be noted that at this stage of the season, there is a wide range of likely yield outcomes for the 2021 season (see State Outlook section) as all the growing season remains in the projected forecast. The current seasonal climate forecast skill will improve towards the end of July. Updating of actual climate and thus shortening of the forecast period will cause the range of yield outcomes to narrow towards the final realised yield at the end of the season.

**POOR CROP CHANCE**

At present, this early in the growing season, there are no regions with an highly increased chance for predicted wheat yield being below the bottom 10% yield of all years (data not shown).

It should be noted that these values are calculated as broad indicators for shire scale. They do not apply to farm level.

**STATE OUTLOOK**

At present, this early in the season, the current state wheat outlook shows a forecast median yield at the start of June of 1.91 t/ha, which is the same as to the long-term median yield (Graph A). There is however, a 10% chance that the state yield could be lower than 1.50 t/ha or higher than 2.21 t/ha. However, keep in mind that it is very early in the growing season and that widespread above average rainfall during the next 2-months is needed to induce good sowing conditions and improve the outlook at shire and regional scales.

At regional level, Southwest Qld (SWQ), Southeast Qld (SEQ) and Central Qld (CQ) (see Map 1), the forecast yield (t/ha) ranges are as follows:

<table>
<thead>
<tr>
<th>Region</th>
<th>Lowest 10%</th>
<th>Median (50%)</th>
<th>Best 10%</th>
<th>Lower median</th>
</tr>
</thead>
<tbody>
<tr>
<td>SWQ</td>
<td>1.25</td>
<td>1.67</td>
<td>2.17</td>
<td>1.67</td>
</tr>
<tr>
<td>SEQ</td>
<td>2.08</td>
<td>2.40</td>
<td>2.78</td>
<td>2.39</td>
</tr>
<tr>
<td>CQ</td>
<td>1.39</td>
<td>1.71</td>
<td>2.71</td>
<td>1.72</td>
</tr>
</tbody>
</table>

Forecast medians for SWQ (1.67 t/ha), SEQ (2.40 t/ha) and CQ of 1.71 t/ha are close to the long-term median expectation for regional wheat yields. The SOI phase of “near zero” at end of May indicates a slightly increased chance for above average rainfall in most parts of the state’s cropping region rainfall over the next 3-months. There remains, however, quite a wide range of possible outcomes that will depend on conditions in the remainder of the growing season. However, given the increasing skill in forecasts as the season progresses, it is advisable to closely monitor progress of the SOI over the next couple of months.
